The copyright owner has no objection to the facsimile reproduction by anyone of the patent document of the patent disclosure, as it appears in the Patent and Trademark Office patent file or records, but otherwise reserves all copyright rights whatsoever.

FIELD OF THE INVENTION

[0003] The present invention relates to the debugging of software and software components.

BACKGROUND

[0004] Most real-world software systems of any significant complexity are written in more than one programming language. For example, an environment may be implemented in Java while an interpreted language may be running on top of Java and need to be debugged. This situation creates significant difficulties for software developers attempting to debug these

systems. This problem is complicated by the fact that there is no standardization in terms of internal structures, such as stack frames, between different programming languages. For example, it is not uncommon for a developer to see stack information not directly related to the software being debugged when encountering a stack frame for one language, when using a debugger intended for another language. As another example, when using a debugger intended for the Java language, a Java stack will not include the XScript (a JavaScript variant with native support for XML) stack, and can sometimes show the set of Java classes that implement the XScript engine (these are part of the environment, but not the software the developer is working on). One multi-language debugger, JSR 45, can only be used to debug languages that are easily transformed into Java and then compiled. This and most other multi-language debuggers won't work with languages such as XScript that where the language will be run by an interpreter or the language can not be mapped directly to Java because, for example, the language has a different data structure. Thus, creating debugging tools that can be applied to software applied to more than one programming language, and running in the same environment, has proved to be extremely difficult.

SUMMARY OF THE INVENTION

[0005] Systems for debugging environment that can be used by software developers working on multi-language systems. The techniques used create a debugging environment that can be uniform across languages, and can seamlessly perform debugging between one or more languages in a multi-language environment. Such a system can have a number of attributes intended to help developers facing debugging problems in multi-language environments.

DETAILED DESCRIPTION

[0006] Systems and methods in accordance with embodiments of the present invention provide a debugging environment that can be used by software developers working on multi-language systems. The techniques used create a debugging environment that can be uniform across languages, and can seamlessly perform debugging between one or more languages in a multi-language environment. Such a system can have a number of attributes intended to help developers facing debugging problems in multi-language environments including:

- **Integrate debugging between two or more languages at the same time.** If more than one language appears on a stack, a developer can see the frames for each language, as well as be able to inspect variables for each language.
- **Nested language debugging.** A developer can debug source code that has several nested languages within a single source file. Mixing several languages in a single source file is becoming an increasingly valuable and popular capability. For example, the emerging ECMAScript for XML languages embeds the XML languages directly in ECMAScript.
- **An extensible architecture.** Support for additional languages can be added to the multi-language debugging environment. For example, using multiple language definitions, a developer can perform debugging in the Java language, Xscript language, the Xquery language, and various Business Process Modeling languages, such as the Business Process Execution Language.

[0007] Each language integrated into a multi-language debugger can include specific support for the stack frame structures and variable representations used in that language. Each new language added to the multi-language debugger can extend the system in at least one of 3 areas:

- **The Integrated Development Environment (IDE).** If the debugger is associated with an IDE, this environment can contain support for the

languages supported by the debugger. These extensions may include appropriate APIs to get at dialog boxes (watch, locals, stack frame, etc), as well as the debugging commands. As an example, many Business Processes Modeling languages will simply be extensions in the IDE that will map to normal Java code, or code in some other compiled or interpreted programming language. In these cases, the extensions may be able to simply create extensions to the IDE environment for the underlying programming language.

- **The Proxy.** In one embodiment of the present invention, the proxy is not required. When implemented, the proxy may be used to implement user interface (UI) commands into the underlying debugging framework requests. The proxy can be used in-process or out-of-process. In the case where a proxy is out-of-process and used as an intermediate between the environment the software is executing in and the debugger, a proxy with the correct mapping between the new language and the underlying language may be used. For example, to add debugging for a new language that maps directly to Java byte codes, the proxy is extended to map between the new language and Java.
- **Runtime messaging infrastructure.** For some languages the debugger should be capable of interacting with the messaging infrastructure. For example, to debug an interpreted language, like Xscript, the debugging may be done on the server side of the messaging infrastructure. In one embodiment, the Runtime messaging infrastructure may interpret language interactions and perform debugging in Java Platform Debugging Architecture (JPDA).

[0008] Throughout the following discussion, an example is developed using the Java language. It will be understood that the invention is equally applicable to any programming language. This example is presented for illustrative purposes only and is not meant to limit the scope, functionality or spirit of any particular embodiment of the invention.

Architectural Overview

[0009] Some embodiments will be comprised of one or more functional components or modules. It will be understood that any particular embodiment of the invention may not require all of the components listed, may use additional components, or may use an entirely different organization without changing the functionality, scope or spirit. Components used in some embodiments can include:

- **A proxy** – In some embodiments a proxy is used between the executing code being debugged and the debugger. In some cases, the proxy serves to improve the efficiency or reduce the overhead associated with debugging protocols. For example, many Java language debuggers use the Java Debugging Interface (JDI), which has a fine-grain API and therefore will create a lot of message traffic between the code under test and the debugger. In this case a proxy can consolidate the contents of some of the messages, potentially reducing messages and overhead.
- **A script engine interface** – A script engine can communicate with the multi-language debugger through a standardized interface. This interface can be used by the multi-language debugger to communicate metadata to the proxy (or possibly directly to the debugger), so the proxy can determine when to call into which debuggable language. As an example, for multi-language support of JavaScript, a Java language debugger may define an interface, possibly called `IdebuggableLanguage`, which is used anytime the script engine is invoked. Typically there is an object in the Java stack that implements this interface, and can translate the Java stack into a JavaScript stack.
- **A debuggable frame** – For each language supported, the scripting engine may use a debuggable frame object, capable of retrieving the script context. As an example, a Java language debugger may define such a standardized frame, possibly known as `IdebuggableFrame`.

- **An interface to the messaging environment** – This is an interface that can be implemented by a runtime-messaging environment that controls the running state of the scripting engines. As an example, a Java language debugger may define a standardized interface, possibly known as `IdebugScriptController`.
- **Script context object** – For each language supported, the scripting engine can use an object to hold a script context. As an example, a Java language debugger may define a standardized object, possibly known as `IcontextHolder`.
- **A debug commands interface** – For each language supported, the script engine can use a standardized interface, which the multi-language debugger uses to call into the different debuggable languages. As an example, a Java language debugger may define a standardized object, possibly known as `IDebugCommands`.
- **A script debug controller** - A script engine may have a static constructor that loads a script debug controller, which may registers itself upon start-up. When the script engine registers itself, the script debug controller may get the following information from the engine: a) the language extensions for each language, b) the classes that implement the script engine, c) information on optional capabilities for the language, and d) the language name. In some cases the controller may store this information internally in a map that goes from extension to script engine. As an example, for a Java language debugger the script debug controller, possibly known as `ScriptDebugController`, is defined in `debugger.jar`

Process Overview

[0010] In some embodiments, when the runtime-messaging infrastructure is started in non-production (debug) mode, a script controller for the debug process is started. This object inspects the system for script engines, and loads them and their configuration information.

[0011] In some embodiments when the runtime-messaging infrastructure starts a debugging session, it will send a message to the proxy. Typically, this message includes a list of languages and language configuration information for the languages supported by the multi-language debugger. In some embodiments, when debugging begins, the debug proxy will talk to the script controller for control flow (e.g. step, continue, pause), and will operate directly on the script engines for debugging information (e.g. stack frames, variable inspection, expressions).

[0012] In some embodiments, after the script engines have all registered themselves, the script debug controller waits until debugging is started. Once debugging commences:

1. The server can send an initialization message to the proxy.
2. The proxy can respond with a packet indicating the languages discovered.
3. The server can send a language response packet during the boot sequence. This packet may include the information used by the script debug controller, such as: a) the language extensions for each language, b) the classes that implement the script engine, c) information on optional capabilities for the language, and d) the language name.
4. The proxy will now send a message indicating the successful completion of the initialization to the runtime messaging server, and will then wait for events.

Breakpoint Hits

[0013] In some embodiments, when a breakpoint is hit, or a step is finished in communications with the script engine will be to the script debug controller. As an example, with Java code, all communications with the script engines will be through JDI calls to the script debug controller.

[0014] For some embodiments, the first breakpoint hit in the underlying language can behave like a normal break. The following process may then occur:

1. The debugger gets the current class, line, and stack and processes the stack through a language filter. If during processing, the debugger encounters a class that implements a script language the following steps may be take: a) if the object derives from a context holder, the debug script controller makes a method call to get the context, and b) the debug script controller will call a method to get the contents of the stack. Continuing the examples for the Java language, the debug script controller will call `getContext` (or some other suitable named method) on the `IcontextHolder` object to get the context and then calls a method `ScriptDebugController.getStack(LanguageExt, Context)` (or some other suitable named method) via JDI, to get a list of `scriptFrames`.
2. All script languages are processed as described above, creating a stack frame list to send back to the debugger.
3. The debugger proceeds to discover and inspect variables in the same way as before.

Current Frame set to Script Frame

[0015] In some embodiments, the following process may occur if the current stack frame is set to a frame controlled by a script engine:

1. Get the "this" object and the frame variables and send them to the client as the list of variables.
2. For each object queried, call a method to get the values of the script variables. Continuing the example for the Java language, a call is made to `IDebuggableLanguage.getVariable()` (or some other suitable named method), to get the `IScriptVariable` (or some other suitable named interface) value. Some possible Java language examples of the results of this operation can be seen in the following table.

Value Type	Value Display	Type Display	If Expanded	In Expression
Simple	<code>getValue()</code>	<code>getType()</code>	-----	Call

				getPrimitiveType() to determine which get* function to call to get the correct value.
Complex	getValue()	GetType() ()	Call getMembers() to get the list of members to display, then call getMember() one each to get the values.	Use getMember to get members, and callMethod to call methods on the value.
Array	getValue()	getType()	Create a list getLength() long, and populate it with calls to getElement()	Use getElement to lookup the values
Other Language	Call into the ScriptDebug Controller to get a resolved ScriptValue and use that.	Call into the ScriptDebug Controller to get a resolved ScriptValue and use that.	Call into the ScriptDebugController to get a resolved ScriptValue and use that.	Call into the ScriptDebugController to get a resolved ScriptValue and use that.
Java	Call getValueObject and treat as ordinary Java Object	Call getValueObject and treat as ordinary Java Object	Call getValueObject and treat as ordinary Java Object	Call getValueObject and treat as ordinary Java Object

Stepping through code

[0016] Some embodiments can step through code using a mechanism analogous to that used in an ordinary (without multi-language support) debugger, except that the debugger will inform the script debug controller when a step is about to begin. In this way, any script engine that is started, and script engines that return from calling into the underlying language (e.g. Java) will be able to stop appropriately. In some cases, script implementation classes are placed into the excludes-filter during a step request.

Continuing

[0017] In some embodiments this operation behaves like a continue in an ordinary (not multi-language) debugger.

Script breakpoint hit

[0018] In some embodiments, when a script breakpoint is hit the following actions can occur:

- The script controller will call a breakpoint method, sending a message indicating the breakpoint hit to the proxy. Continuing the Java language example, the controller can call into a method with a name, such as, `ScriptDebugController.Break()` to send the message to the proxy.
- The Proxy can then freeze the thread, and perform any required communications. In the Java example these communications can use function calls via JDI.
- When the user decides to continue, the debugger will unfreeze the thread and send a Continue, StepIn, StepOver, StepOut, etc., packet as appropriate.

[0019] In some embodiments, if the user hits Stop instead of Continue, the thread can be un-frozen, no network packet will be sent, and the thread may be forced to throw an exception used for killing threads. Alternatively, such actions by the user can be temporarily blocked.

Pause

[0020] In some embodiments, when the user hits Pause, the thread will be paused. The debugger can then look to see if the stack is currently in scripting or the underlying language (e.g. Java) code. One of the following actions may then be taken:

1. If the stack is in the underlying language code, the process is complete. In some cases, this situation is treated in the same way hitting a breakpoint is treated.
2. If the stack is in script code, a pause method is called on the script engine interface and the execution of the scripting language will continue until it hits a stopping point, when a pause method is called on the script debug controller. Continuing the Java language example, when a pause() method on the `IdebuggableLanguage` interface is called, the scripting language will continue until it hits a stopping point, at which point the engine calls `ScriptDebugController.Pause()`.

[0021] In some embodiments, when a pause is called on a script language while it is waiting on some synchronization object, it will be treated as a normal thread in the underlying language (e.g. Java), which can prevent deadlock scenarios.

Breakpoints

[0022] In some embodiments, information in breakpoint packets can use a suitable extension or other indicator to identify the language type being executed. In some cases, the absence of the extension can indicate the underlying language (e.g. Java) is being used. If a breakpoint is not in the underlying language the following actions may be taken:

1. Send a message to the script debug controller telling it to set a breakpoint.
2. The script debug controller will look up the proper extension or indicator and set a breakpoint using the method available for that language.
3. The script debug controller will then send a message indicating the success or failure of setting the breakpoint.

In some embodiments several types of breakpoints are supported, which can include:

Source Breakpoints	This is the ordinary type of breakpoint that goes on a source file/line number
Method Breakpoint	This breakpoint is hit when a certain method is called
Watch point	This breakpoint is hit when a variable is either read or written.

[0023] It should be noted, that depending on the details of the embodiment, any language may be able to support a sub-set of the available breakpoint types for any given language. Returning a true or false to a query for that type can indicate the support for a particular breakpoint type. For example, a true or false can be returned for a method, `featureEnabled()` (or some other suitable name), when called with a variable indicating the break point type, such as, `SOURCE_BREAKPOINT_SUPPORT`, `METHOD_BREAKPOINT_SUPPORT`, or `WATCH_POINT_SUPPORT`

An Example: Interfaces

[0024] The following examples show sets of interface definitions for two embodiments, developed using the Java language. It will be understood that the invention is equally applicable to any programming language. This example is presented for illustrative purposes only and is not meant to limit the scope, functionality or spirit of any particular embodiment of the invention.

Interface Definition 1

```

/**
 * The script controller will be an object that interoperates with the scripting languages
 * to bring you script debugging. The way this will work is each language engine will have
 * an instance of the <code>IScriptController</code>, and the <code>IScriptController</code>
 * will have list of all the <code>IDebuggableLanguage</code> interfaces.
 */
public interface IScriptController
{
    static int RESUME_CONTINUE = 0;
    static int RESUME_STEP_IN = 1;
    static int RESUME_STEP_OUT = 2;
    static int RESUME_STEP_OVER = 3;
    static int RESUME_STOP = 4;
}

/**
 * This is what a running script will call when it wants to break. This is a waiting call,

```

```

* that will not return until the thread has been told to continue. The frames parameter should
* be a list of <code>IDebuggableLanguage$IScriptFrame</code>.
*
* @param frames - should be the frame list for the current script context.
*
* @return the return value tells the scripting engine what command resumed the break.
*/
public int Break();

/**
 * this is what the scripting lanuguage calls when it's time to pause itself.
 *
 * @return the return value tells the scripting engine what command resumed the pause.
 */
public int Pause(int pauseID);

/**
 * This is what a script engine must call when starting execution. This is how the
 * engine will know if the thread is currently in the middle of a step or not.
 *
 * @return the return value tells the scripting engine what kind of execution we are
 * in the middle of.
 */
public int StartScript();

/**
 * This is what a script engine must call when resuming execution. This is how the
 * engine will know if the thread is currently in the middle of a step or not.
 *
 * @return the return value tells the scripting engine what kind of execution we are
 * in the middle of.
 */
public int ResumeScript();

/**
 * processes the variable on script engine that created it. This will be called by a script engine
that
 * needs to process an expression or a variable that was created in another script engine or in
Java.
 */
public IDebuggableLanguage.IScriptValue
processScriptValue(IDebuggableLanguage.IScriptValue value);

/**
 * This tells the script controller that a breakpoint that was previously un-resolvable has
 * now been resolved.
 */
public void breakpointProcessed(IDebuggableLanguage.IBreakpointInfo bpi);

/**
 * This gets the stack frames for the script language specified, using the context specified.
 *
 * @param langExt -- This is the language extension for the language we are inspecting.
 * @param context -- This is the language context we are investigating.
 *
 * @return an array of the stackframes this yeilds.
 */
IDebuggableLanguage.IScriptFrame[] getStack(String langExt, Object context);
}

/**
 * This interface is used to get a context object for a given frame. The way this
 * will work is that the Proxy will go down the stack frame, looking for objects that
 * derive from IScriptContextHolder. When it comes across such a class, it will get the
 * context from the frame and pass it to the DebugScriptController. It is possible for
 * many script frames to all have the same context. In this case, the frame will only
 * get passed to the DebugScriptController once.
 */
public interface IScriptContextHolder
{
    public Object getContext();
}

/**
 * A scripting engine must implement this interface in order to be able to set itself up
 * to debug in the KNEX framework.
 *
 * NOTE: Kill will work the same way for script languages as it does for Java execution. An
 * exception will suddenly be thrown that should kill everything.
 */

```

```

Network Messages

[0025]As has already been discussed, some embodiments use facilities in the runtime-messaging environment to perform debugging operations on network messages. This capability is demonstrated here by example shown in the table below developed using the Java language. In another embodiment, method calls may be made via the native debugging infrastructure JDI. Methods are called on the ScriptController via JDI to do continues and other such tasks. Breakpoints are executed by hitting actual Java breakpoint and are then translated in the proxy to script breakpoint. Thus, breakpoints reduce to java breakpoints. JDI sends a message to the proxy in the underlying JDI protocol. For example, a packet may be sent from the server to the proxy that includes meta-data for a scripting language. The meta-data is used to determine whether to treat the language as a scripting language or to treat the language as a native language. It will be understood that the invention is equally applicable to any programming language. This example is presented for illustrative purposes only and is not meant to limit the scope, functionality or spirit of any particular embodiment of the invention.

Message	Sender	Meaning	Parameters
SetBreakpoint	Proxy	Trying to set a script breakpoint.	File – File name Line – Line number Language Ext – Language Extension
SetMethodBreakpoint	Proxy	Trying to set a breakpoint on a method	Class – Class name (or file name is language doesn't have classes) Method -- Name of the

			method to set a breakpoint on Parameters – The parameters for the method to set a breakpoint on. This disambiguates in the case of multiple methods with the same name but different parameters Language Ext – Language Extensions
BreakpointSet	Runtime-messaging environment	Breakpoint is set	Status – Did the breakpoint get set Error -- Error message if it failed
BreakHit	Runtime-messaging environment	A Script hit a breakpoint	File – the file name Line – the line number
Continue	Proxy	A script should resume	ContinueType – whether this should continue with a step or a continue
Pause	Runtime-messaging environment	Tells the proxy a script has gotten to a safe place and paused	PauseID – This is the ID we use to map a pause the thread it was requested on.

[0026] The foregoing description of preferred embodiments of the present invention has been provided for the purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise forms disclosed. Many modifications and variations will be apparent to one of ordinary skill in the art. The embodiments were chosen and described in order to best explain the principles of the invention and its practical application, thereby enabling others skilled in the art to understand the invention for various embodiments and with various modifications that are suited to the particular use contemplated. It is intended that the scope of the invention be defined by the following claims and their equivalence.
